molecular clusters in the broad sense that the term is commonly understood today comprise an enormous class of species extending into virtually every important area of

chemistry naked metal clusters transition metal carbonyl clusters hydrocarbon cages such as cubane C_8H_8 and dodecahedrane $C_{20}H_{20}$ organometallic cluster complexes enzymes containing Fe-S or MoFe-S 4_43_4 cores high polymers based on carborane units and of course the many kinds of polyhedral borane species so large is the area spanned by these diverse classes that any attempt to deal with them comprehensively in one volume would to say the least be ambitious and also premature we are presently at a stage where intriguing relationships between the various cluster families are becoming apparent particularly in terms of bonding descriptions and despite large differences in their chemistry an underlying unity is gradually developing in the field for example structural changes occurring in Fe-S cores as electrons are 4_4 pumped in and out in some measure resemble those observed in boranes and carboranes the cleavage of alkynes via incorporation into carborane cages and subsequent cage rearrangement a sequence familiar to boron chemists is a thermodynamically favored process which may be related to the behavior of unsaturated hydrocarbons on metal surfaces analogies of this sort have drawn attention from theorists and experimentalists
